SPECIFICATION

1. Title of the Invention
Operation Handle for Floor Cleaner

2. Scope of Claim for a Patent

An operation handle in which a machine body comprising a rotation brush, a dust collecting box for receiving dust picked up by a rotation thereof and pivot shafts for supporting the machine body while said rotation brush is provided with a rotation, has a long handle, the peripheral face of a short shaft mounted on a reinforcement shaft of the machine body containing an oil groove, a rotation short cylinder being fit to the short shaft, and the outer peripheral face of the rotation short shaft being tapered so that a bent pipe end at the bottom end of the handle being fit to the tapered face tightly.

3. Detailed Description of the Invention

For a cleaner provided with a rotation brush, a dust collecting box and a rolling shaft for giving rotations to a rotation brush, contained within a flat machine box whose bottom face is open to be capable of changing its direction to the right or the left on the floor only by pivoting the operation handle slightly, the bottom end of the handle is bent a little and that bent portion is mounted on a mounting portion of the machine body such that it is capable of pivoting. However, in the pivot mechanism portions already proposed through some applications, a short shaft is attached to a reinforcement shaft mounted on the machine body and the pivot shaft, whose top end is bent at a predetermined angle, is installed on that short shaft and a handle is attached to that pivot shaft.

Such a handle pivot mechanism requires at least surplus parts for the pivot shaft portion and thus, there is such a disadvantage that the quantity of assembly steps and faults are increased.

From such viewpoints, the present invention has a feature in that a short cylinder is installed on a short shaft mounted on a reinforcement shaft of the machine body such that it is capable of pivoting freely around the short shaft and the peripheral face of the short cylinder is tapered so that the bent bottom end of the handle is fit to the tapered face directly. Consequently, unnecessary parts disappear from the pivot portion of the handle and thus, not only the above-described fault is eliminated but also the weight of the machine is reduced, so that the cleaner becomes further easy to use.

As for the embodiment shown in the attached drawings, a cleaner comprises a rotation brush 2, a dust collecting box and rotation wheels 4, 4 for driving the rotation brush, provided within a machine box 1 whose bottom face is open. A handle 6 is attached to a reinforcement shaft 5 stretched inside the lateral faces of the machine box.

The handle 6 is elongated for a person to be capable of reciprocating the cleaner on the floor while he is standing upright and for convenience for transportation, this can be disassembled to several short pieces.

The handle 6 operates the cleaner in conditions in which it is tilted at an appropriate angle to the cleaner. For the cleaner to advance in the direction of a twisted handle to the right or the left when the cleaner is pushed with the end of the handle 6 gripped in the condition that it is tilted, a short shaft 7 is provided at the bottom end of the handle 6, that is, a portion which supports the handle by means of a reinforcement shaft 5 and a short cylinder 8 is fit to the short shaft 7 such that it is able to pivot freely around the short shaft 7. A taper is formed on the peripheral face of the short cylinder 8 and then, an end 9 tilted at about 30° at the bottommost end of the storage type handle 6 is squeezed along the tapered face.

To prevent the short cylinder 8 from slipping out of the short shaft 7, a friction plate 10 is provided at the top end of the short shaft and a lubricant collecting groove 11 is provided in the peripheral face of the short shaft 7 to maintain the pivot of the short cylinder 8.

In order to mount the short cylinder 8 which pivots in conditions in which the long handle 6 is tilted and keep the handle standing upright easily on the machine body as shown in FIG. 1, apparently it is necessary to provide its pivot performance with some restriction when it stands upright and provide an opposite end of the short shaft 7 with a mechanism facilitating that standing upright, taking into account matters relating to gravity center. As a result, a leaf spring 12 is attached under the reinforcement shaft 5 and the spring pressure of that leaf spring is applied to the bottom end of the short shaft 7. The bottom end of the short shaft 7 is formed into flat faces 13, 13 at an angle considering the matters relating to the gravity center. The leaf spring 14 is erected along both ends of a concave groove formed in the machine box 1 such that it engages the reinforcement shaft 5 and when the short cylinder 8 stands upright on the top end of the leaf spring 14, its bottom flange portion 15 makes a pressure contact so as to restrict the rotation performance of the short cylinder 8. However, to ensure the operation further, projecting rows 16,16 which expand at a specific angle with respect to the reinforcement shaft 5 are formed in the inner face of the leaf spring 14. When the flange portion 15 of the short cylinder 8 comes in between the two projecting rows 16, 16, the standing upright of the handle 6 is ensured.

4. Brief Description of Drawings

The accompanying drawings indicate the embodiment of the operation handle of the present invention. FIG. 1 is a perspective view of the entire floor cleaner, FIG. 2 is a partially broken side sectional view of the handle mounting portion.
